#### Gaussian Elimination is not Optimal

VOLKER STRASSEN®

Received December 12, 1968

1. Below we will give an algorithm which compares the coefficients of the product of two square matrices A and B of order a from the coefficients of A and B with less than 4.7 s<sup>3/2</sup> arithmetical operations (all logarithms in that and B with less than 4.7 s<sup>3/2</sup> arithmetical operations (all logarithms in compare are for low 2, but less (2 v 3.2). It was almost includes algorithms for inverting a relative of lower a society as system of a loss or quasire quiet from its friend and an artist of order s cit. all requiring less than count s<sup>3/2</sup> arithmetical operations, This force is done to consease with the recent of Kiveryea and Kooverse.

SECURIBANA [1] that Gaussian elimination for solving a system of linear equations is optimal if one restricts oneself to operations upon rows and columns as a whole. We also note that WINOGRAD [2] modifies the usual algorithms for matrix multiplacation and invention and for solving systems of linear equations, trading roughly half of the multiplications for additions and subtractions.

By a no absump to that D. Burstanyers for incurring discussions about the rewest

subject and Sr. Coox and D. Falkert for encouraging me to write this paper.

We define algorithms s<sub>m,1</sub> which multiply matrices of order we.<sup>2</sup>, by induction on 8, s<sub>m,6</sub> is the usual algorithm for matrix multiplication (requiring w<sup>2</sup> multiplications and we'(w - t) additions). s<sub>m,6</sub> a heready being known, define s<sub>m,1</sub> as follows:

i.i. as follows:
If A. B are matrices of order ss 2<sup>k+1</sup> to be multiplied, write.

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}, \quad B = \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix}, \quad AB = \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{21} \end{pmatrix}$$
where the  $A_{12}$   $B_{13}$   $C_{14}$  are matrices of order  $m 2^{h}$ . Then compute

 $I = \langle A_{11} + A_{23} \rangle \langle B_{11} + B_{23} \rangle,$  $II = \langle A_{21} + A_{22} \rangle B_{21},$ 

III =  $A_{11}(B_{12} - B_{22})$ , IV =  $A_{22}(-B_{11} + B_{21})$ , V =  $(A_{11} + A_{12})B_{22}$ ,

 $V = (A_{11} + A_{12}) B_{22},$   $VI = (-A_{11} + A_{22}) (B_{11} + B_{12}),$  $VII = (A_{12} - A_{22}) (B_{21} + B_{22}),$ 

\* The results have been found while the author was at the Department of Statistics of the University of California, Berkeley, The author wishes to thank the National Science Foundation for their sumorit (NNF GP-2446). Gaussian Elimination is not Optimal

 $C_{11} = I + IV - V + VII,$   $C_{11} = II + IV,$  $C_{12} = III + V.$ 

 $C_{ss} = 1 + \Pi \Pi - \Pi + V\Pi$ , using  $\mathbf{x}_{m,s}$  for multiplication and the usual algorithm for addition and subtraction

using  $s_{m,k}$  for multiplication and the usual algorithm for addition and subtraction of matrices of order se 2<sup>k</sup>.

By induction on k one easily sees.

Fact l:  $u_{m,k}$  computes the product of two matrices of order w  $2^k$  with  $w^k$   $2^k$  multiplications and (5+m)  $w^k$   $2^k - 6(w$   $2^k$  additions and subtractions of numbers. Thus one may multiply two matrices of order  $2^k$  with  $2^k$  numbermultiplications and less than 6.  $2^k$  additions and subtractions.

Fast 2. The product of two matrices of order n may be computed with <4.7 ·n<sup>3</sup>47 arithmetical operations.
Prod. Put

$$k = (\log n - 4),$$
  
 $m = (n2^{-k}) + 1,$ 

n ≤ m 2\*.

Imbedding matrices of order w into matrices of order #42 reduces our task to that of estimating the number of operations of an s. By Fact 1 this number is

 $(5+2m)m^37^6-6(m2^6)^3$ =  $(5+2(m2^{-6}+4))(m2^{-6}+4)^32^6$ 

 $< 2\pi^2(7/8)^4 + 12.03\pi^2(7/4)^4$ 

(here we have used  $16\cdot 2^k \le n)$ 

 $= (2(8/7)^{\log n - k} + 12.03(4/7)^{\log n - k}) n^{\log r}$   $\leq \max_{i} (2(8/7)^{i} + 12.03(4/7)^{i}) n^{\log r}$ 

≤ 4.7 · n<sup>3/g?</sup>

by a convexity argument.

then

We now turn to matrix inversion. To apply the algorithms below it is necessary to assume not celly that the matrix is invertible but that all occurring divisions make sense (a similar assumption is of course necessary for Gaussian elimination). We define algorithms A., which invert matrices of order se2, by induction

We define algorithms  $\beta_{m,k}$  which invert matrices of order  $w2^n$ , by induction on  $k: \beta_{m,k}$  is the usual Gaussian elimination algorithm.  $\beta_{m,k}$  already being known, define  $\beta_{m,k+1}$  as follows:

If A is a matrix of order  $m 2^{k+1}$  to be inverted, write

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}, \quad A^{-1} = \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix},$$

V. STRASSEN: Gaussian Elimination is not Optimal

where the  $A_{11}$ ,  $C_{12}$  are matrices of order  $\approx 2^{h}$ . Then compute

$$I = A_{11}^{-1},$$
  
 $\Pi = A_{11}I,$   
 $\Pi = IA_{12},$   
 $IV = A_{21}III,$   
 $V = IV - A_{22},$   
 $VI = V^{-1}.$ 

 $C_{11} = V^{-1},$   $C_{11} = III \cdot VI,$  $C_{11} = VI \cdot II,$ 

 $VII = III \cdot C_{01}$ ,  $C_{11} = I = VII$ ,

 $C_{ii} = I - VI$  $C_{ii} = -VI$ 

using  $u_{m,k}$  for multiplication,  $\beta_{m,k}$  for inversion and the usual algorithm for addition or subtraction of two matrices of order  $w^{2^k}$ .

By induction on & one easily sees

Nos. 24 1067

Faut 3.  $\beta_{m,k}$  computes the inverse of a matrix of order  $m 2^k$  with  $m 2^k$  divisions,  $\leq \frac{n}{2} m^2 2^k - m 2^k$  multiplications and  $\leq \frac{n}{2} (3 + m) m^2 2^k - 2 (m 2^k)^k$  additions and subtractions of numbers. The next Faut follows in the same way as Fact 2.

Fact 4. The inverse of a matrix of order n may be computed with  $< 5.64 \cdot n^{\log 2}$  arithmetical operations.

Similar results hold for solving a system of linear equations or computing a determinant (use  $\text{Det } A = (\text{Det } A_{11}) \text{ Det } (A_{22} - A_{21} A_{12}^{-1} A_{12})$ ).
